Problem Statement

Amateur street cricket players in Pakistan face a significant challenge due to the absence of accessible formal coaching and advanced training resources. This limitation obstructs their progress in honing their batting skills and impedes their capacity to make well-informed decisions during gameplay.

Existing System

Street cricket stands as one of the most beloved forms of amateur cricket in Pakistan. In this informal setting, players spontaneously assemble teams and engage in spirited matches. Unlike the international broadcast level, where sophisticated technology like Hawk-Eye provides supervision and analysis, amateur players must rely on their experience and intuition.

Despite the profound cricketing passion in Pakistan, especially within the street cricket culture, the absence of accessible coaching resources poses a significant impediment to the growth of emerging talents. Street cricket players primarily rely on self-assessment and occasionally capture their performances on smartphones for later reflection.

However, the absence of real-time analytical tools is striking. The current ecosystem lacks a system for tracking and scrutinizing critical factors such as ball trajectory, speed, and the quality of shots executed by street cricket enthusiasts. This lack of data-driven insights leaves players to make decisions based purely on intuition and anecdotal knowledge, limiting their ability to make informed choices on the field.

Literature Survey

Introduction

Pakistan holds a significant place in the world of cricket, renowned for nurturing world-class players who often emerge from the vibrant culture of street cricket. The purpose of this literature review is to explore existing research and technological advancements related to cricket coaching and performance improvement. We seek to identify gaps in the literature that our proposed cricket batting improvement application can address, aiming to empower aspiring cricketers and revolutionize street cricket training in Pakistan.

Technology in Cricket

The utilization of technology in cricket is a well-established practice. Advanced technological innovations have had a global presence in cricket broadcasts worldwide. One of the most prominent among these technological advancements is the Hawk-eye system. Hawk-eye technology was created by Dr. Paul Hawkins and it was developed by the engineers of Roke Monor Research Limited [1]. It is the means to determine the LBW (leg before wicket) decision through ball tracking, proving to be a vital part of the DRS (decision review system). The Hawk-Eye system consists of an extensive network of cameras positioned around the entire cricket pitch, complemented by additional motion sensors to precisely gauge the ball's speed [2]. These collected data inputs are then transmitted to a sophisticated statistical algorithm responsible for calculating the ball's trajectory. While immensely effective in cricket analysis, it's worth noting that Hawk-Eye systems are both cost-intensive and intricate, making them less accessible and challenging for the general public to comprehend.

Current Systems and Mobile Applications

Over the years, several coaching options have emerged in the realm of cricket, including mobile applications and websites that provide extensive coaching content through courses and tutorials [3]. However none of these are able to cater specifically to the unique needs of street cricket players in Pakistan. A cricket coach is expected to provide real-time analysis and feedback, which is particularly crucial for refining batting skills in the ever-changing and dynamic context of street cricket. Existing applications have yet to incorporate this essential aspect, leaving a noticeable gap in meeting this specific need. An illustrative mobile application, such as fulltrack.ai, demonstrates how simplicity can aid players without overwhelming intricacies [4]. This app, tailored for bowlers, offers real-time ball tracking, measures ball speed, and determines the trajectory, spin, or swing of each delivery. However, there remains an evident requirement for a comparable application designed specifically for cricket batsmen.

A machine learning approach to Shot Classification

Cricket videos require unequivocally accurate understanding of the type of shot being played for effective coaching and learning. Classifying the type of shot played by a player using learning algorithms has always been an arduous task. The factors that contribute to classifying a shot to one and not the other vary slightly in terms of footwork and the players pose. In 2010, Yao and Fei-Fei presented a paper[5] focused on the interaction activities involving objects and human poses. Their research introduced a novel random field model aimed at encoding human poses during interactions with objects. To address this problem, they formulated it as a learning task for the

model. The key components of this approach involved summarizing human activity poses and identifying body parts.

Due to the similarity between different batting shots, manual feature extraction from video frames is tedious. The most effective way of feature extraction is through deep neural networks. When it comes to video analysis, Convolutional Neural Networks (CNN) emerge as one of the most formidable models, akin to their success in image classification. CNN's prowess in classification accuracy surpasses that of traditional video classification algorithms [6]. What sets CNN apart is its ability to automatically extract relevant features from video frames, eliminating the need for manual feature selection—a requirement in many other video classification techniques. CNN employs a variety of layers, including the convolutional layer, which employs moving filters or kernels to traverse the video frames. These filters scan through the 2D matrices representing the frames, performing dot multiplications at specific regions and storing the results in another matrix. This process enables CNN to capture intricate patterns and features within video data, making it a powerful tool for video classification tasks.

Anik Sen[7] introduces a hybrid neural network architecture for classifying 10 distinct cricket batting shots within videos, using a self-created dataset due to the unavailability of a public dataset with comparable uniqueness and variety. The hybrid CNN-GRU model, adapted from a pretrained VGG16 model, achieved an impressive accuracy of 93%, highlighting the advantages of transfer learning and model fine-tuning when working with limited data. Furthermore, plans are in place to expand the dataset and make it publicly accessible for further experimentation and accuracy enhancements. This dataset, known as the CricShot10 dataset, can serve as the baseline for our development of a deep learning algorithm to classify cricket shots.

Conclusion

This literature review underscores the significance of technology in cricket, exemplified by the Hawk-Eye system. While highly effective, such technology can be complex and costly. Examining the current coaching landscape, we observed the emergence of mobile applications and websites providing comprehensive coaching content. However, a conspicuous gap persists in catering to the unique needs of street cricket players in Pakistan, who thrive in an ever-changing and dynamic environment. The importance of real-time analysis and feedback, particularly for refining batting skills, was underscored as an essential yet unmet need.

The importance of machine learning and shot classification in cricket analysis is evident, with Convolutional Neural Networks (CNNs) emerging as powerful tools for video analysis. A notable project, CricShotClassify, achieved a 93% accuracy in classifying cricket shots using a hybrid CNN-GRU model, highlighting the potential of transfer learning and model fine-tuning with limited data.

In essence, our literature review sets the stage for our proposed cricket batting improvement application, which aims to bridge coaching gaps, offer real-time analysis, and empower street cricket players in Pakistan, revolutionizing their training experiences.

Proposed Solution

A mobile app empowering amateur cricket players to enhance their batting skills. This user-friendly app, acting as a virtual coach, offers a fresh perspective on their gameplay.

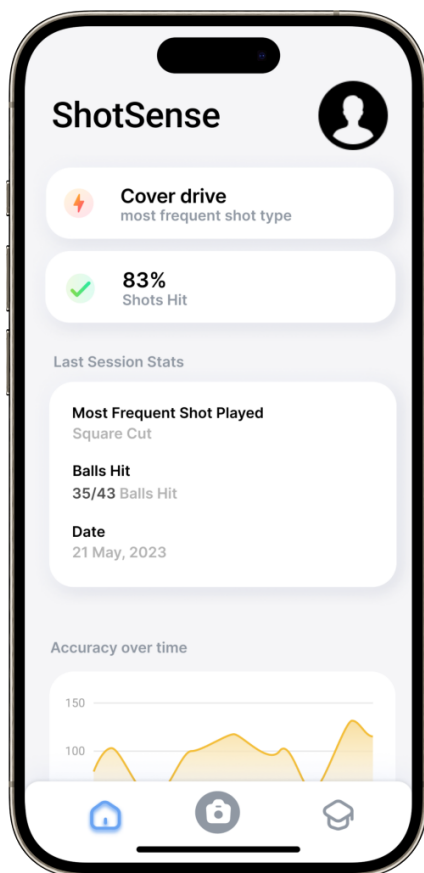

Through real-time pose and footwork tracking, players gain a comprehensive understanding of their technical proficiency. Additionally, we plan to implement machine learning algorithms for classifying shot types, enabling players to make informed decisions.

This app provides valuable insights, highlighting areas of improvement, such as shot placement on the bat and shot selection. It essentially brings a coach to their smartphones, enhancing the excitement and enjoyment of street cricket

Wireframes

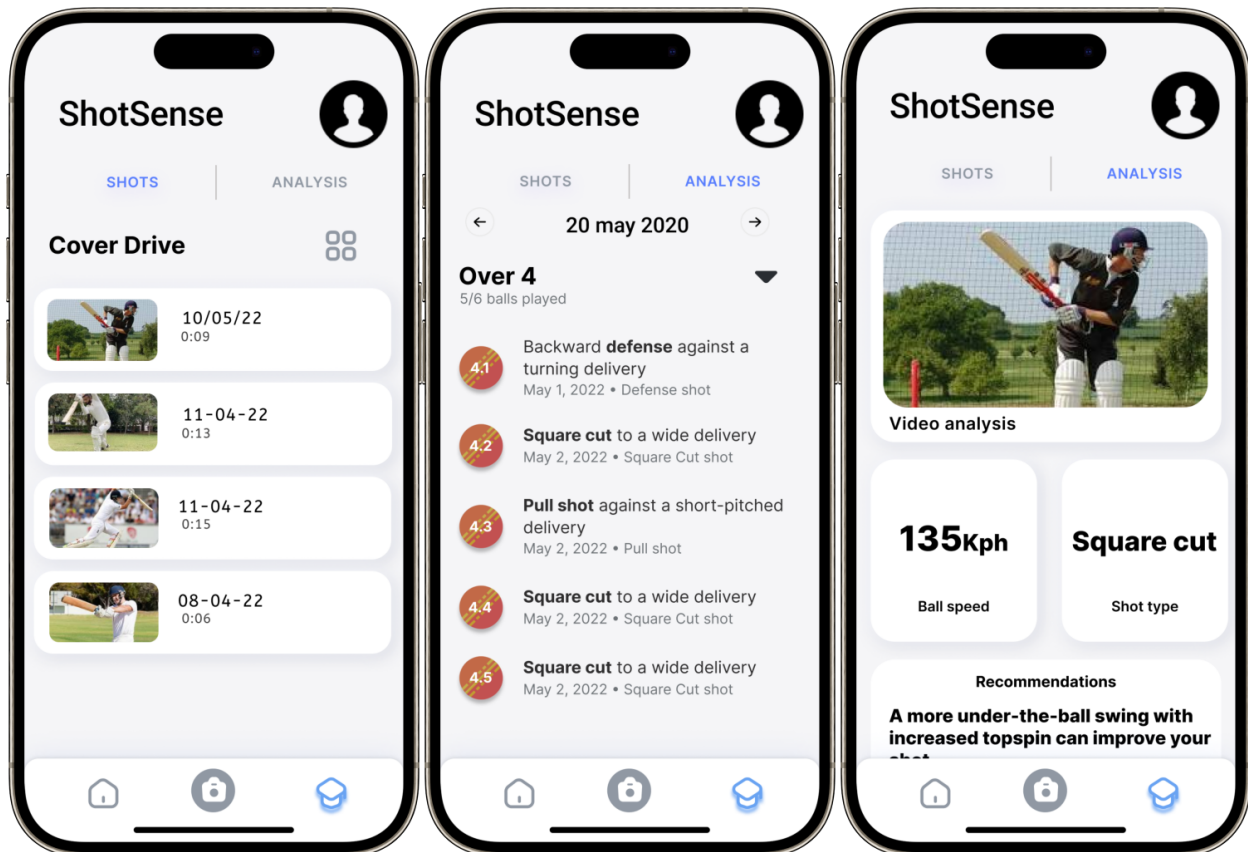

Homepage

The homepage is the overview of all time analytics and statistics of your batting performances overtime. Account information can also be viewed from this page

Profile

Classified shots are displayed in the *Shots* tab and different shot types can be viewed by filter. In the *Analysis* tab, you can review your previews balls per over, clicking on a ball played takes you to details about that specific ball, displaying all the information that is gathered for that particular ball played.

Deliverables

The deliverables for this project encompass a range of application features designed to ensure the functionality of the application. These features will utilize cutting-edge machine learning models for shot classification and posture recognition, making it an invaluable tool for amateur cricket players. The ultimate objective of this project is to augment players' skills, elevate coaching techniques, and offer valuable insights through data-driven analytics.

The comprehensive list of deliverables for this project is as follows:

Shot Classification Model

In this module, we aim to develop our custom deep learning model that correctly classifies 10 shots from videos. The first step would be to gather data and label it. Then we will define preprocessing procedures that correctly identify the frames for model classification. The model will be trained on this dataset and will be tested on real life cricket shots recorded on a mobile phone.

Model Implementation on TF Lite for Local Inference

We will convert our model to TensorFlow Lite or Pytorch Mobile, which can then be integrated into our mobile application for local inference of cricket shots. Our main goal is to try and do the processing locally without using cloud technologies.

Processing Videos from Mobile for Pose Estimation

This module involves the processing of videos locally to visualize posture and stance for our users. Videos that are captured using the mobile device's camera are then preprocessed, which may involve resizing, normalization, and frame extraction. These videos can be accessed by the users to get a unique visualization of their play style.

Annotating Key Points for Pose Estimation

In this module we will collect key value data for players. This includes values for joints such as elbows, knees, their footwork and more. This data will be used to enrich the data collected from the video. This will then be used to create suggestions for players on how to correct their posture.

Ball Tracking to Show Lines

This deliverable focuses on object detection and object tracking. Our aim would be to detect the ball trajectory and outline the path taken by the ball. This will also allow us to recognise the area where the shot is played for better description of the shot. Using the path of the ball, this module will also aim to classify if the ball was hit or missed.

Analytics

The goal of this deliverable is to provide a dashboard of analytics to our users utilizing all the historical data we have been collecting previously to show player statistics. These statistics will include but not be limited to most frequently played shots, accuracy statistics, total number of deliveries faced, statistics on shot decision etc. These offer insights and visualizations to aid players in their performance analysis.

Mobile Application

Our final deliverable is the complete mobile application that delivers a fully functional and user-friendly mobile application that integrates all the above features seamlessly.

Technologies

Mobile App Frameworks

Flutter

We will be using flutter to create the mobile interface that will be the dashboard of our software, enabling it to work with our machine learning algorithms

TensorFlow Lite or Pytorch Mobile

TensorFlow Lite and PyTorch Mobile are two popular frameworks for deploying machine learning models on mobile devices. TensorFlow Lite is preferable because it is a more mature framework with a larger community of users

Cloud Storage

Cloud Storage

Google Cloud Storage is a robust, cloud-based object storage service renowned for its exceptional scalability, unwavering high availability, and unmatched data durability. This platform will be instrumental in securely storing all of our players' valuable footage.

Computer Vision Libraries

OpenCV and Byte Track

OpenCV and Byte Track are both powerful, open-source, cross-platform libraries that encompass a vast array of computer vision algorithms. These libraries offer versatile tools and capabilities, making them invaluable for a diverse range of applications. These include tasks such as face detection, object tracking, and image processing. Leveraging these libraries, we intend to precisely track the trajectory of the ball. This will enable us to generate comprehensive analytics, enhancing our ability to analyze and understand the dynamics of the shot played.

Pose Estimation

YOLO-pose and OpenPose

YOLO-Pose and OpenPose are two prominent approaches for human pose estimation. YOLO-Pose is a real-time, single-stage method capable of simultaneously estimating the poses of multiple individuals within an image. It is trained on the extensive COCO dataset, encompassing over 200,000 meticulously annotated images of people.

Database

PostgreSQL or Firebase

PostgreSQL and Firebase are both excellent choices for storing data, but they cater to different needs. PostgreSQL is a robust and traditional relational database management system (DBMS), ideal for structured data like user profiles and their associated file links, complete with timestamps and additional attributes.

Data Analytics

Tableau or Power BI

These tools excel with its user-friendly interface and extensive feature set, enabling users to effortlessly translate ball tracking and shot classification data into insightful graphics and reports. These technologies will be instrumental in creating comprehensive analytics, harnessing the data's full potential. We will be using their API's to create tailored dashboards for the users

Business Model

The proposed business model for the app is a subscription-based system supplemented by tailored in-app advertisements aimed at the cricket community. This model not only ensures a sustainable and consistent revenue stream for the app but also provides users with access to premium features, enhancing their experience. The subscription fees collected will be allocated to various critical aspects, including covering computational resources, server maintenance, and ongoing operational costs. Additionally, a portion of the revenue will be earmarked for continuous app improvement and the development of new features to stay competitive and meet evolving user needs. This strategic allocation of funds not only supports the app's longevity but also facilitates its growth and innovation.

Project Methodology

Project Proposal Phase

- Form the project group, select the external supervisor, and finalize the project.
- Develop the Project Proposal Document, which includes the objective of the project, statement of the problem, description of the existing system, literature survey, proposed solution, phases of the project, project methodology, cost-benefit analysis, and references.
- Deliverable: Proposal Document
- Deliverable: Proposal Presentation

Requirement Analysis Phase

- Conduct a detailed analysis of the problem or current system through literature survey and data gathering.
- Formalize the findings in the form of a Software Requirement Specification (SRS) document, Use Case document, and Test cases.
- Start learning the technologies to be employed in the project.
- Deliverable: Requirement Analysis Document

Design Phase

- Develop the Design Document, which includes the system architecture, class diagram, sequence diagram, and database diagram.
- Deliverable: Design Document

Implementation Phase

- Begin the development of the mobile app, focusing on the implementation of machine learning algorithms for shot classification, pose estimation, ball tracking, shot quality assessment, and decision-making feedback.
- Deliverable: Implementation Document with Screen Shots and Reports depicting 30% functionality of the system

Testing and Deployment Phase

- Conduct thorough testing of the developed app, ensuring it aligns with the Software Requirement Specification (SRS) Document.
- Deploy the app on Android and iOS platforms.
- Deliverable: Testing and Deployment Document

Final Presentation

- Present the Analysis, Design, and Implementation Document before the Faculty Panel.
- Deliverable: Final Presentation
